

SUPPLEMENT TO “IDENTIFYING RATIONAL TYPES IN UNKNOWN
ENVIRONMENTS”
APPENDIX 2: MICROSTRUCTURE AND COMPETING HAZARDS IN COLOMBIA

HUMBERTO BERNAL

Economics Program, Universidad Colegio Mayor de Cundinamarca and Ph.D. in Economics, Universidad de los Andes

This supplement presents in full detail the microeconomic results summarized in Section 2.3 of the main paper (“Microstructure and competing hazards in Colombia”). It documents the CNMH/SIEVCAC data, the construction of the analytical sample, the sample-selection test, the multinomial logit (MNL) model of kidnapping outcomes, specification diagnostics and robustness checks, and the cause-specific Cox proportional hazards models of resolution timing. All estimates were reproduced from the Stata scripts in the `Appendix_2/` replication package (Section S7).

S1. DATA AND SAMPLE CONSTRUCTION

Individual kidnapping records come from the Information System on Events of Violence in the Colombian Armed Conflict (SIEVCAC), maintained by the National Center of Historical Memory (CNMH) (CNMH, 2026, 2013). The replication package includes the merged case–victim file `stata/data/Data_merge.dta` ($N = 39,369$ victim-level records) and the estimation-ready export `stata/data/analytical_sample.csv` ($n = 1,133$ rows after outcome filters and variable construction).

S1.1.0.0. *Universe and sequential filters*

Table S1.1 summarizes the sample flow reported in the main text. The universe comprises all documented kidnapping victims in the merged CNMH export. The first filter retains extortionate kidnappings (`TipodeSecuestro = EXTORSIVO`) with a valid event date. The second filter requires an observable liberation outcome (excluding ND, OTRO, and NA in `TipodeLiberación`). The third filter requires complete covariates for estimation; eight cases with missing geographic zone are dropped, yielding $n = 1,125$.

S1.2.0.0. *Outcome variable*

The dependent variable `Y_Resultado` classifies each extortionate episode into four mutually exclusive outcomes (reference category: Payment):

- **Payment** ($Y = 1$): ransom or exchange paid (PAGO, CANJE, and related codes).
- **Rescue** ($Y = 3$): liberation by state forces (RESCATE).
- **Escape or release without payment** ($Y = 0$): FUGA or release under external pressure without ransom.
- **Death** ($Y = 2$): victim killed in captivity (MUERTO EN CAUTIVERIO, ASESINADO).

Table S1.2 reports the distribution in the estimation sample.

Economist, professor of the Economics Program at the Universidad Colegio Mayor de Cundinamarca and graduate of the Ph.D. in Economics from the Universidad de los Andes, Colombia.

TABLE S1.1
ANALYTICAL SAMPLE CONSTRUCTION

Stage	n	Share of prior stage
Universe (merged CNMH records)	39,369	—
Valid event date	37,617	95.5%
Extortionate typology	11,270	30.0%
Observable outcome	1,133	10.1%
Complete covariates	1,125	99.3%

Note. Extortionate share of universe: $11,270/39,369 = 28.6\%$. Estimation share: $1,125/39,369 = 2.9\%$. Eight cases with missing geographic zone are dropped at the final stage. *Source:* Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

TABLE S1.2
OUTCOME DISTRIBUTION IN THE ESTIMATION SAMPLE

Outcome	Count	Share
Payment (reference)	515	45.8%
Rescue	474	42.1%
Escape or release without payment	123	10.9%
Death in captivity	21	1.9%
Total	1,125	100.0%

Note. Estimation sample $n = 1,125$. Payment is the MNL reference category. *Source:* Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S1.3.0.0. Covariates

The covariate vector $\mathbf{X}_{i,m} \in \mathbb{R}^{26}$ in the main text comprises four blocks (all coded as indicator variables with stated reference categories):

1. **Perpetrator** ($\mathbf{G}_i$): FARC (ref.), ELN, paramilitaries, common delinquency/other.
2. **Victim profile** ($\mathbf{V}_i$): high income (ref.), middle class, vulnerable, public sector, unknown.
3. **Context** ($\mathbf{C}_{i,m}$): geographic zone (metropolis ref., Andean, Caribbean, Pacific/conflict, East/jungle) and historical period (pre-1998 ref., 1998–2002, 2003–2010, post-2011).
4. **Tactics** ($\mathbf{T}_i$): modus operandi, collective vs. individual structure, GAULA intervention, victim sex, captivity duration category (express ≤ 2 days ref., short ≤ 30 days, long > 30 days, missing), and $\ln(\text{total victims per case})$.

Standard errors are clustered at the municipal level (373 clusters). Variable construction rules are implemented in `microstructure_replication.do` and `sample_selection_robustness.do`.

S2. SAMPLE-SELECTION TEST

Because only 10.1% of extortionate cases have observable outcomes, a binary logistic model was estimated on the full extortionate stratum ($n = 11,270$), with dependent variable `Missing_Outcome = 1` when the liberation type is unobserved (Little and Rubin, 2020). Table S2.1 summarizes the main findings as odds ratios with cluster-robust standard errors by municipality.

The test rejects complete randomness of missing outcomes while supporting the internal validity of the structural estimators: substantive covariates do not predict missingness, and the remaining bias is territorial (metropolitan overrepresentation).

TABLE S2.1
ATTRITION LOGISTIC REGRESSION RESULTS

Covariate	OR	<i>p</i> -value	Significance
Non-metropolitan zones	1.9–2.2	< 0.001	1%
Period 1998–2002	1.8	0.001	1%
Victim profile	—	> 0.10	—
ln(total victims per case)	—	> 0.10	—

Note. Estimated on the extortionate stratum ($n = 11,270$) before dropping missing outcomes. Cluster-robust standard errors by municipality. OR > 1 indicates higher odds of an unobservable outcome. Non-metropolitan zones comprise Andean, Caribbean, Pacific, and East/jungle categories. Victim-profile and scale covariates are not predictive at the 10% level; geography and the 1998–2002 period show systematic attrition. The Significance column reports the highest conventional level (1%, 5%, 10%); “—” denotes not significant at 10%. *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S3. MULTINOMIAL LOGIT MODEL

S3.1.0.0. *Specification*

With Payment as the base category ($Y = 1$), the MNL estimates

$$\ln \left(\frac{\Pr(Y_{i,m} = j \mid \mathbf{X}_{i,m})}{\Pr(Y_{i,m} = 1 \mid \mathbf{X}_{i,m})} \right) = \alpha_j + \mathbf{X}_{i,m}' \boldsymbol{\beta}_j, \quad j \in \{0, 2, 3\}. \quad (\text{S3.1})$$

The main specification uses cluster-robust standard errors at the municipality level (Wooldridge, 2010).

S3.2.0.0. *Model fit*

The model is jointly significant: Wald $\chi^2(78) = 5,250.34$, $p < 0.001$; McFadden pseudo- $R^2 = 0.18$.

S3.3.0.0. *Full estimation results*

Table S3.1 reports the complete MNL specification: all 26 covariates for the three non-payment outcomes (Escape, Death, Rescue), with cluster-robust standard errors, z -statistics, p -values, and 95% confidence intervals. The baseline outcome is Payment ($Y = 1$).

N	1,125					
Wald $\chi^2(78)$	5,250.34					
$Prob > \chi^2$	0.0000					
Pseudo R^2	0.1847					

Note. Relative risk ratios (RRR) reported. Baseline outcome is Payment. Cluster-robust standard errors at the municipality level (373 clusters; $n = 1,125$). p -values in parentheses are two-sided. Significance at 5%: $|z| > 1.96$. *Source:* Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S3.4.0.0. Key relative risk ratios

Table S3.2 summarizes the three headline findings in Section 2.3 of the main paper, expressed as relative risk ratios ($RRR = \exp(\hat{\beta})$). The corresponding rows in Table S3.1 are Peace process/current (Escape), public-sector victim (Escape), and short/long duration (Rescue).

S3.5.0.0. Predicted probabilities (margins)

Table S3.3 reports average marginal predicted probabilities from the main MNL (unconditional margins).

TABLE S3.2
SELECTED MULTINOMIAL LOGIT RELATIVE RISK RATIOS

Outcome	Covariate	RRR	p-value	Significance
Escape	Post-2011 period	11.28	< 0.01	1%
Escape	Public-sector victim	3.92	< 0.01	1%
Rescue	Short captivity (≤ 30 d)	0.18	< 0.001	1%
Rescue	Long captivity (> 30 d)	0.08	< 0.001	1%

Note. Base category: Payment. $RRR = \exp(\hat{\beta})$. Duration categories are relative to express captivities (≤ 2 days). Period contrast: post-2011 vs. pre-1998. The Significance column reports the highest conventional level (1%, 5%, 10%); “—” denotes not significant at 10%. *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

TABLE S3.3
AVERAGE PREDICTED PROBABILITIES FROM THE MAIN MNL

Dimension	Category	Pr($\cdot$)
<i>Rescue by geographic zone</i>		
	Metropolis	0.465
	Andean	0.447
	Pacific	0.414
	East/jungle	0.424
	Caribbean	0.343
<i>Death by perpetrator group</i>		
	FARC	0.002
	ELN	0.007
	Paramilitaries	0.026
	Common delinquency	0.071

Note. Unconditional margins from `margins` after the main MNL ($n = 1,125$). Rescue probabilities decline away from metropolitan nodes; death probabilities rise as logistical retention capacity falls. *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S4. MNL DIAGNOSTICS AND ROBUSTNESS

S4.1.0.0. *IIA test*

The Hausman–McFadden (Hausman and McFadden, 1984) SUEST generalization (Weesie, 1999) compares the full four-outcome model with a restricted model that excludes Death. The test does not reject independence of irrelevant alternatives: $\chi^2(1) = 0.14$, $p = 0.706$.

S4.2.0.0. *Coefficient stability*

Three specifications are compared: (i) main model with municipal clusters; (ii) robust standard errors without clustering; and (iii) specification without duration categories.

Table S4.1 reports two coefficients from the Death equation.

TABLE S4.1
MNL ROBUSTNESS COEFFICIENTS

Covariate	$\hat{\beta}$ (Death equation)		
	Main	Robust SE	No duration
Common delinquency (vs. FARC)	4.15	4.15	4.15
Collective structure (vs. individual)	2.46	2.46	2.46

Note. Municipal clusters in Main and No duration; heteroskedasticity-robust standard errors in Robust SE. Coefficients are stable across specifications: both remain positive and significant at the 1% level in all three columns ($p < 0.01$; No duration $p < 0.001$). *Source:* Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S4.3.0.0. Death-rate heterogeneity

Raw death rates in the estimation sample are 7.9% for common delinquency and 0.2% for the FARC. A two-sample proportion test (FARC vs. common delinquency) rejects equal rates: $z = -5.68$, $p < 0.001$.

S5. CAUSE-SPECIFIC COX PROPORTIONAL HAZARDS

S5.1.0.0. Specification

Following Cox (1972) and the competing-risks framework of Bradburn, Clark, Love, and Altman (2003), four cause-specific Cox models are estimated on *Días de Cautiverio* (days in captivity). In each model, one outcome defines the event of interest and the remaining three outcomes are treated as right-censored. The cause-specific hazard is

$$h_j(t | \mathbf{X}) = h_{0j}(t) \exp(\mathbf{X}'\tilde{\beta}_j), \quad j \in \{\text{Payment, Rescue, Death, Escape}\}, \quad (\text{S5.1})$$

with the same covariate blocks as the MNL but excluding duration categories, which would be collinear with the time axis. The Cox subsample comprises $N = 461$ cases with positive captivity duration and complete covariates (602 cases with missing duration and 64 zero-day captivities are excluded; Breslow ties). FARC is the reference perpetrator group. Cluster-robust standard errors are reported.

S5.2.0.0. Estimation results

Table S5.1 reports all four cause-specific equations (Payment, Rescue, Death, and Escape/release without payment). Table S5.2 lists the coefficients emphasized in Section 2.3 of the main paper.

TABLE S5.1: Cause-Specific Cox Proportional Hazards Results (Four Equations)

Note. Hazard ratios (HR) with cluster-robust *p*-values in parentheses (two-sided). * *p* < .05; ** *p* < .01; *** *p* < .001. Duration categories are excluded (collinear with the time axis). The Cox subsample (*N* = 461) drops 602 cases with missing duration and 64 zero-day captivities

TABLE S5.2
SELECTED CAUSE-SPECIFIC COX HAZARD RATIOS

Equation	Covariate	HR	p-value	Significance
<i>Payment equation</i>				
	Paramilitaries	4.28	< 0.001	1%
	Common delinquency	1.71	0.021	5%
	ELN	1.19	0.317	—
<i>Payment and Rescue equations</i>				
	Public-sector victim (Payment)	0.20	< 0.001	1%
	Public-sector victim (Rescue)	0.24	0.001	1%
<i>Post-2011 period</i>				
	Post-2011 (Payment)	0.51	0.035	5%
	Post-2011 (Rescue)	4.86	< 0.001	1%

Note. Rows match Table S5.1 (rounded for the narrative). Reference perpetrator group: FARC. $HR = \exp(\tilde{\beta})$; $HR > 1$ indicates faster resolution, $HR < 1$ slower resolution. The Significance column reports the highest conventional level (1%, 5%, 10%); “—” denotes not significant at 10%. Payment speed falls 49% post-2011 ($1 - 0.51$); Rescue hazard multiplies by ≈ 4.86 . *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

TABLE S5.3
RESCUE PROBABILITY BY GAULA INTERVENTION AND DURATION

GAULA intervention	Express	Short	Long
No	0.64	0.28	0.14
Yes	0.72	0.35	0.19

Note. Unconditional margins from the Rescue cause-specific Cox model. Duration categories: express (≤ 2 days), short (≤ 30 days), long (> 30 days). *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

(Breslow ties). Payment and Rescue coefficients match Section 2.3 of the main paper; Death and Escape equations use the same covariate vector (`cox_only.do`). The Death equation has only 13 events: several HRs hit numerical bounds (reported as 0.000) owing to quasi-complete separation; its Wald statistic is omitted from interpretation. Pacific zone, unknown victim profile, military incursion, unknown modus, and sex indicators are estimated but omitted for parity with the main-text table layout. *Source:* Authors’ own calculations based on CNMH/SIEVCAC microdata (Section S1). Software: Stata 19 (StataCorp, 2025).

S5.3.0.0. *GAULA intervention and cumulative rescue*

Unconditional margins from the Rescue Cox model show that GAULA intervention raises the predicted rescue probability at each duration category (Table S5.3).

Cumulative rescue probabilities by day 100 appear in Table S5.4 (exported in `outputs/Datos_Graficas_Cox.xlsx`).

S5.4.0.0. *Mortality*

The MNL yields unconditional average predicted death probabilities of 0.002 (FARC) and 0.071 (common delinquency) in Table S3.3. The corresponding cause-specific Cox margins

TABLE S5.4
CUMULATIVE RESCUE PROBABILITY AT DAY 100

Perpetrator group	Pr(Rescue by day 100)
Paramilitaries	0.33
ELN	0.30
FARC	0.29

Note. Computed from cause-specific survival curves ($1 - S_{100}$) in `outputs/Datos_Graficas_Cox.xlsx`. *Source:* Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). *Software:* Stata 19 (StataCorp, 2025).

TABLE S6.1
MECHANISM INPUTS AND REPLICATION FILES

Mechanism object	Main-text result	Package file
Prior μ_0 over types θ_K	MNL outcome distribution	<code>microstructure_replication.do</code>
Terminal payment technology	RRR by victim profile	<code>sample_selection_robustness.do</code>
Arrival rates $\lambda_j(\theta_K, t)$	Cox cause-specific HRs	<code>microstructure_replication.do</code>
GAULA effectiveness γ_t	GAULA $\times$ duration margins	<code>outputs/Datos_Graficas_Cox.xlsx</code>
Sample validity	Attrition logit, IIA, robustness	<code>sample_selection_robustness.do</code>

Note. The MNL supplies the static type map; the Cox models supply dynamic resolution hazards that feed the daily public signal ζ_t in the MDG process. All paths are relative to `Appendix_2/stata/`.

Source: Authors' own calculations based on CNMH/SIEVCAC microdata (Section S1). *Software:* Stata 19 (StataCorp, 2025).

reported in Section 2.3 of the main paper are 0.002 and 0.079 ($\approx 35\times$ and $\approx 40\times$, respectively). Both specifications preserve the same ordering: mortality rises as logistical retention capacity falls.

S6. RELEVANCE FOR THE MECHANISM

S6.1.0.0. *Scope*

This section maps the microeconomic results to the mechanism-design model (Section 2.3 of the main paper). It introduces no new estimates.

S7. REPRODUCIBILITY

All results in this supplement are reproduced by Stata scripts included in the replication package that accompanies this document (folder `Appendix_2/` when delivered with the thesis). Scripts use paths relative to `stata/`. Requirements: Stata 19 or later. Estimated runtime: 5–15 minutes on a standard laptop.

1. Set the working directory to `stata/` and run `microstructure_replication.do`. The script constructs variables, estimates the attrition logit, the main MNL, robustness checks, the SUEST IIA test, and four cause-specific Cox models.

2. Run `sample_selection_robustness.do` to replicate Tables S2.1–S4.1 and the IIA test.
3. Run `cox_only.do` (or `microstructure_replication.do`) to replicate all four cause-specific Cox models and export `outputs/cox_appendix_rows.txt`.
4. Inspect `outputs/Datos_Graficas_Cox.xlsx` for survival and hazard curves (Tables S5.3 and S5.4).
5. (Optional) Compile this document from `tex/` with `pdflatex` and `bibtex`.

S7.1.0.0. Raw CNMH files

The merged file `Data_merge.dta` was built from CNMH exports `CasosSE_2025_09.xlsx` and `VictimasSE_202509.xlsx`. Place raw files in `stata/data/raw/` and follow `README.txt`. The checkpoint analytical `sample.csv` ($n = 1,133$ rows; $n = 1,125$ after dropping eight missing zones) is included for inspection.
